

USING GIT IN FI-SSF PROJECT

Present by: Ho Quoc Vuong (RBVH/ETI4)

Agenda

Overview: What is Git?

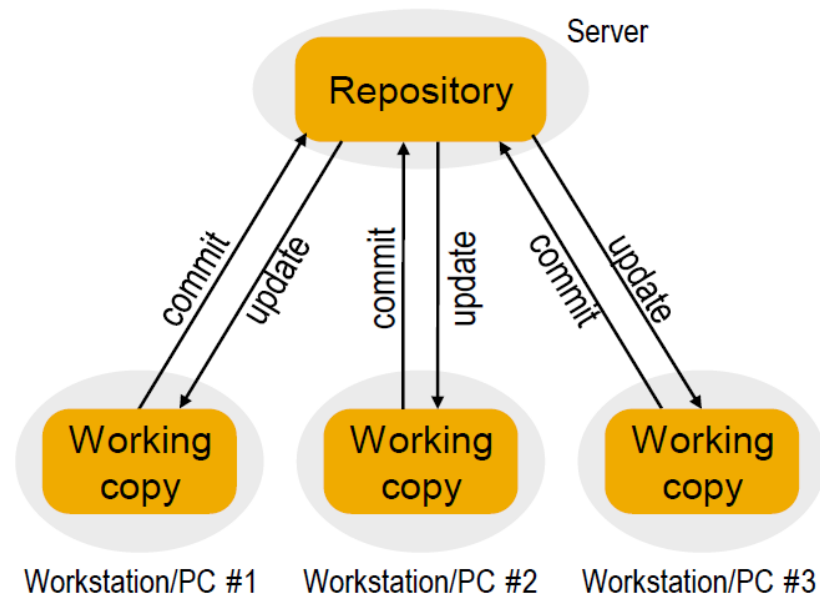

Git basics: Clone, Save, Stage, Commit, Stash

Combining Branches: Fast-Forward Merging, 3-Way Merging, Rebasing, Hard Resets, Mixed Resets

Working with Remotes: Pushing, Fetching, Pull

What is Git?

- ▶ Developed in 2005 by Linus Torvalds
- ▶ DVCS (**D**istributed Version Control System)
- ▶ Every developer get his or her own individual repository

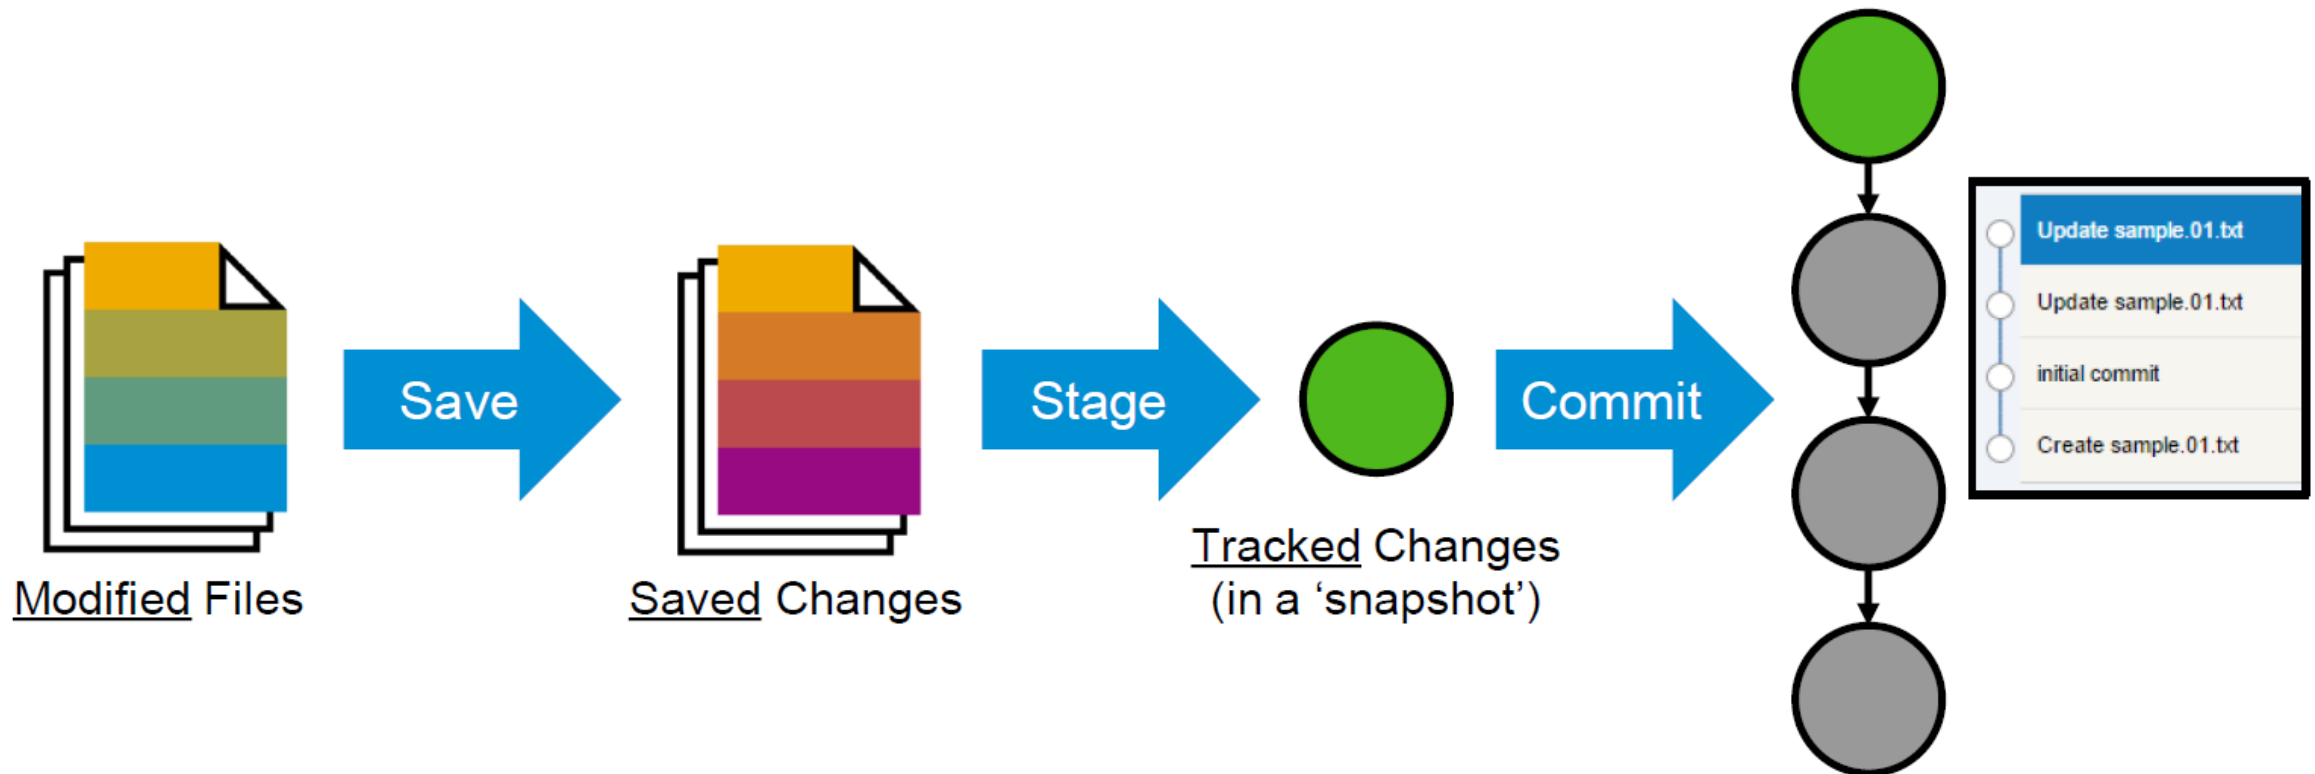

Git Clone

- ▶ Take an entire source code repository
- ▶ An additional branch Master is created

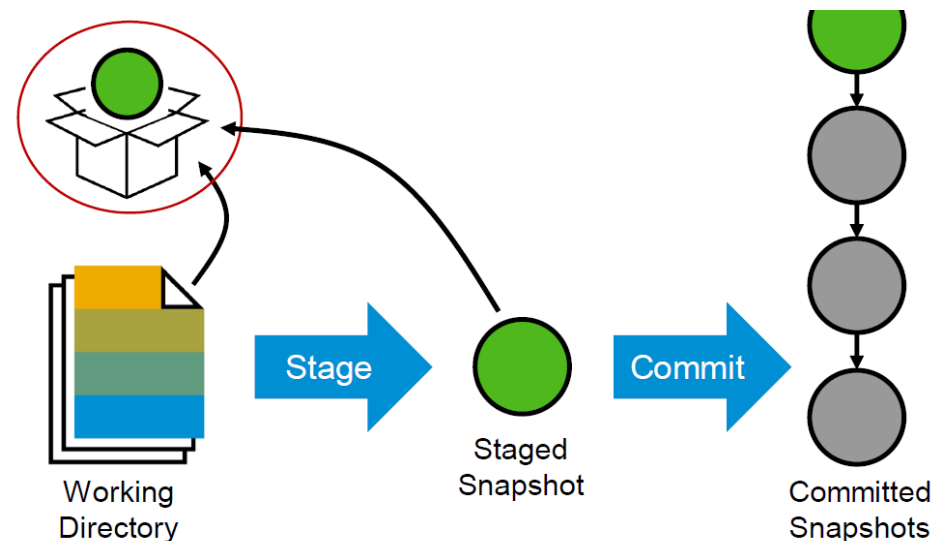

Save, Stage, Commit

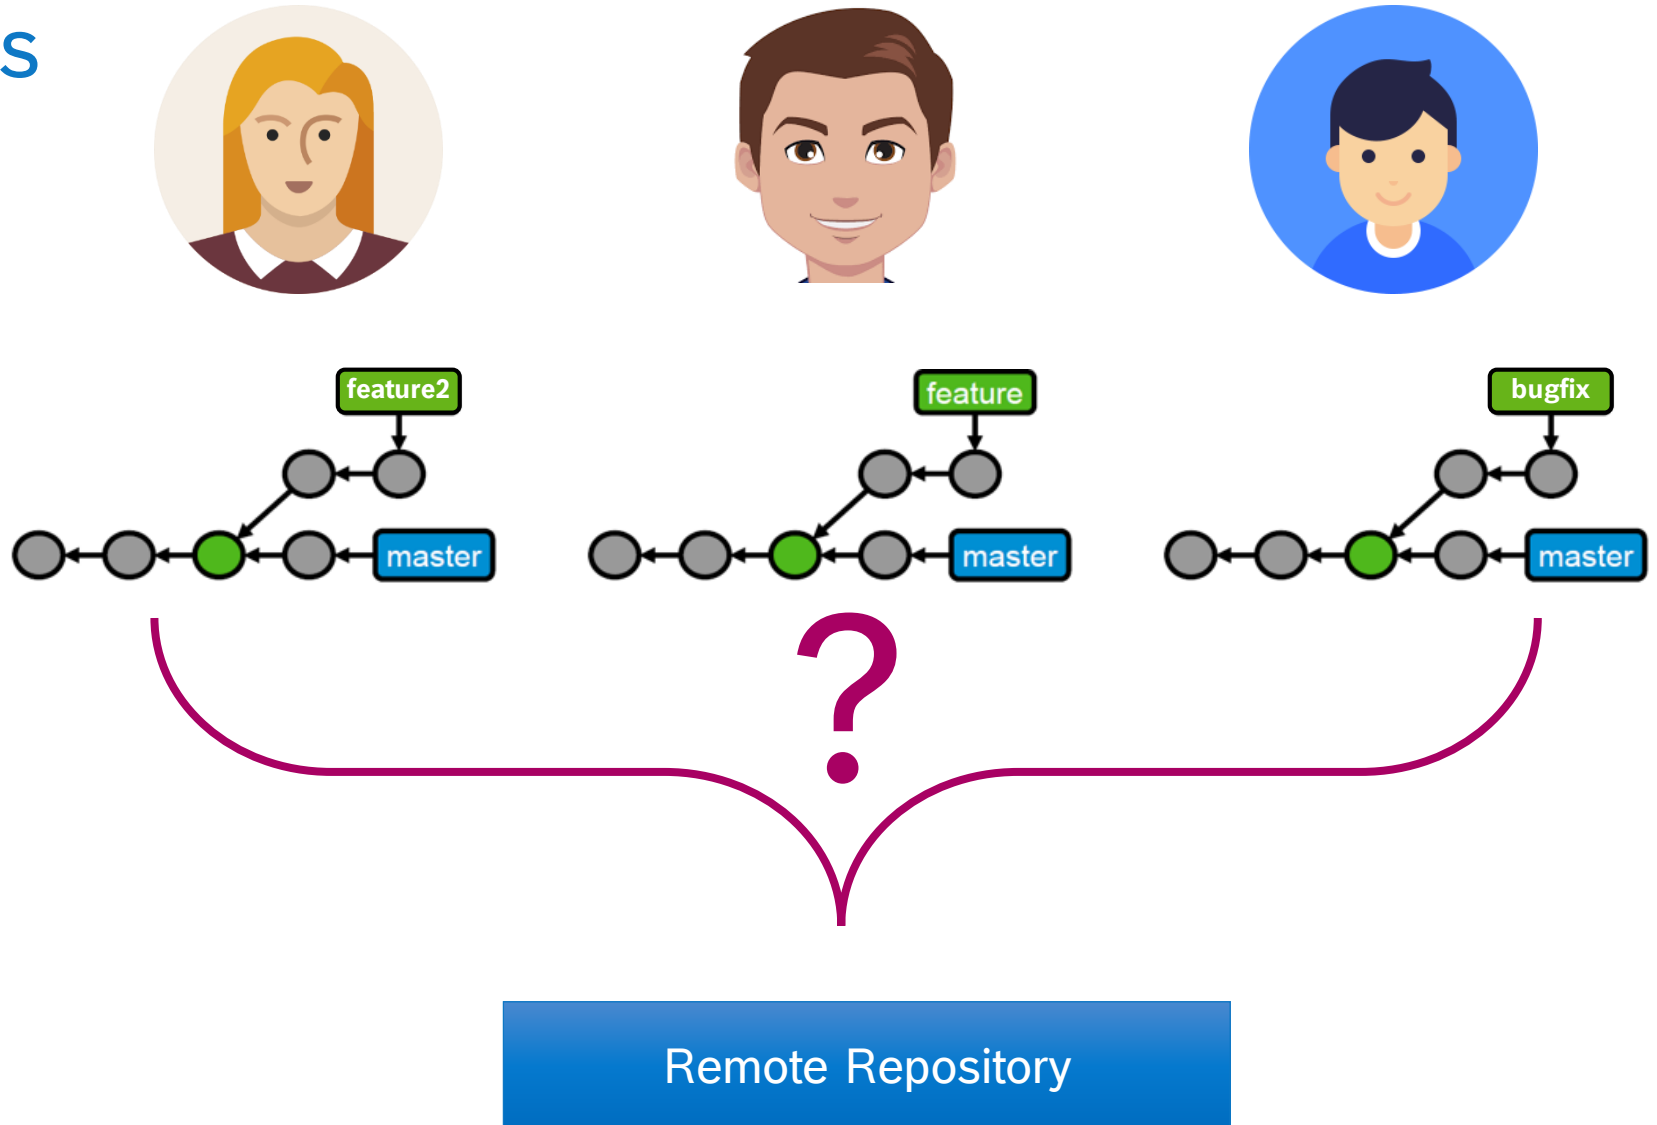

Stash

- ▶ Stashing is the way to save the changes locally, to retrieve back later.
- ▶ There are 4 options to retrieve stash:
 1. Apply: takes the top most stash in the stack and apply it
 2. Pop: similar to stash apply but it deletes the stash from the stack after it is applied
 3. Drop: Remove all stash from the stack
 4. Cancel: Do nothing

Combining Branches

- Fast-Forward Merge & 3-Way Merge
- Rebase
- Mixed Reset

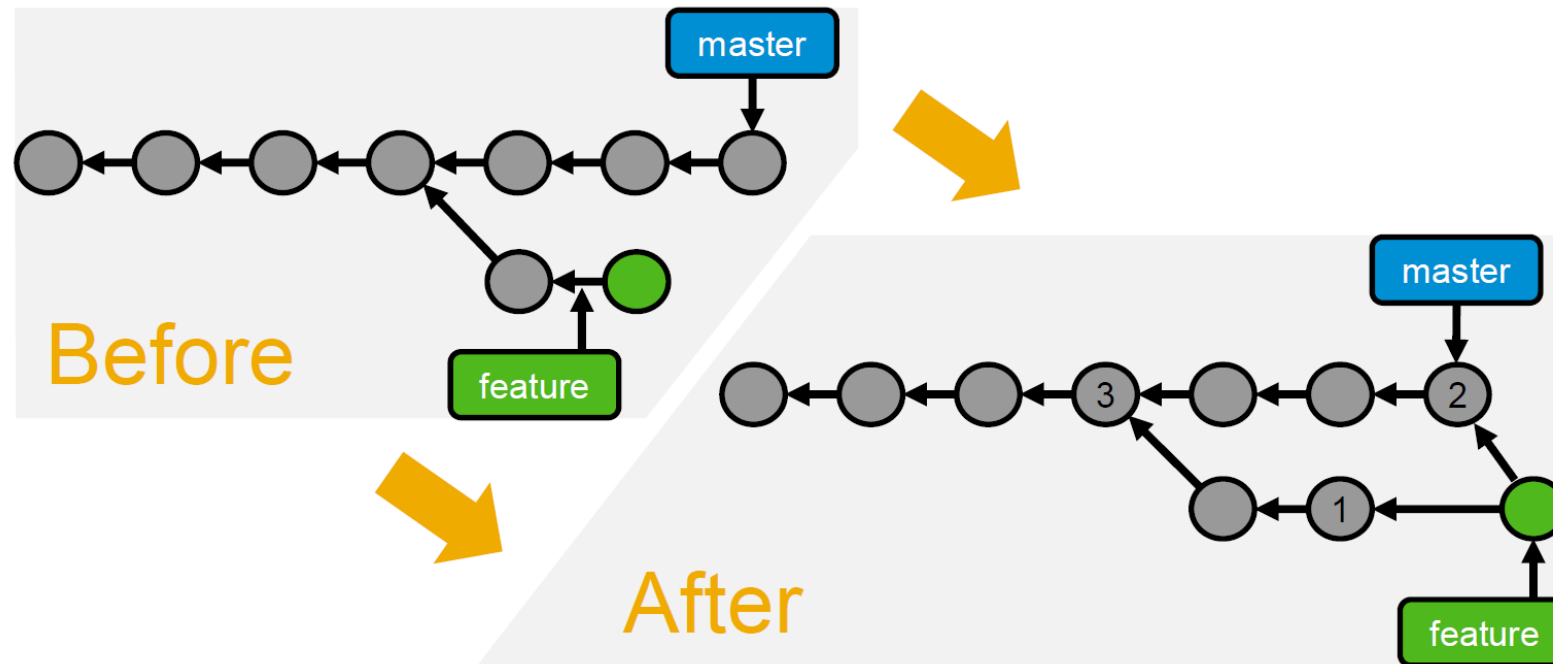

Fast-Forward Merge

- ▶ When you merge a branch onto one ahead of it (in sequence)

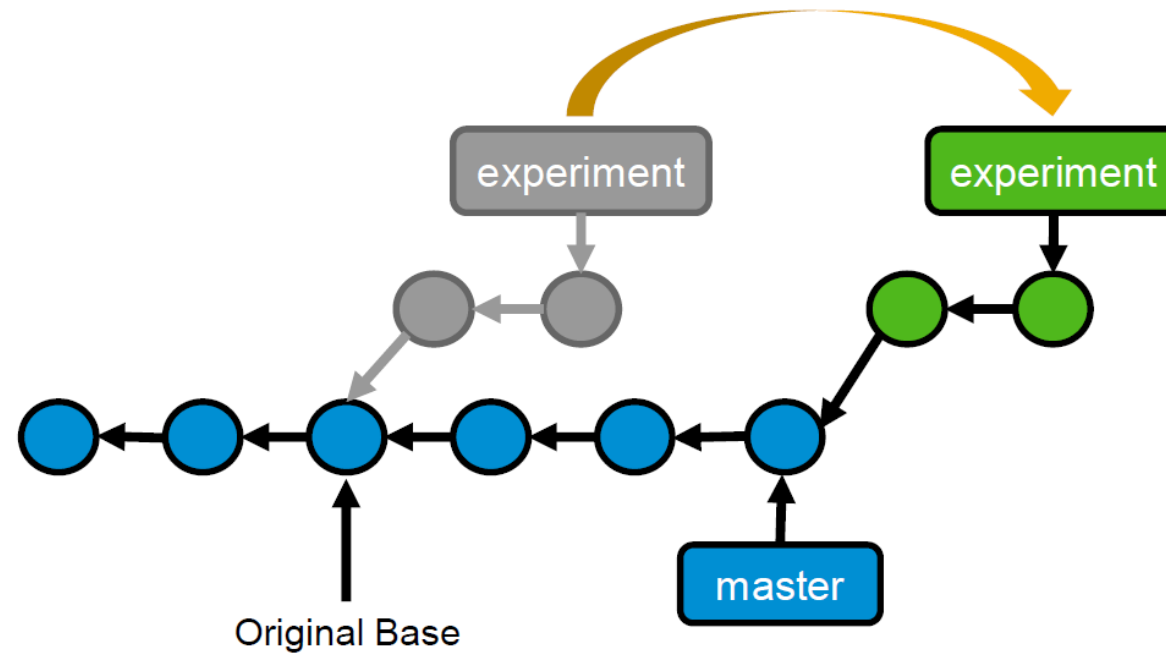

3-Way Merge

- ▶ Combine 2 branches which is separate Overview single commit
- ▶ Create new merge commit, branch pointer points to different commit.

Rebase

- Pickup all commits associated one branch, put them on the top of another branch

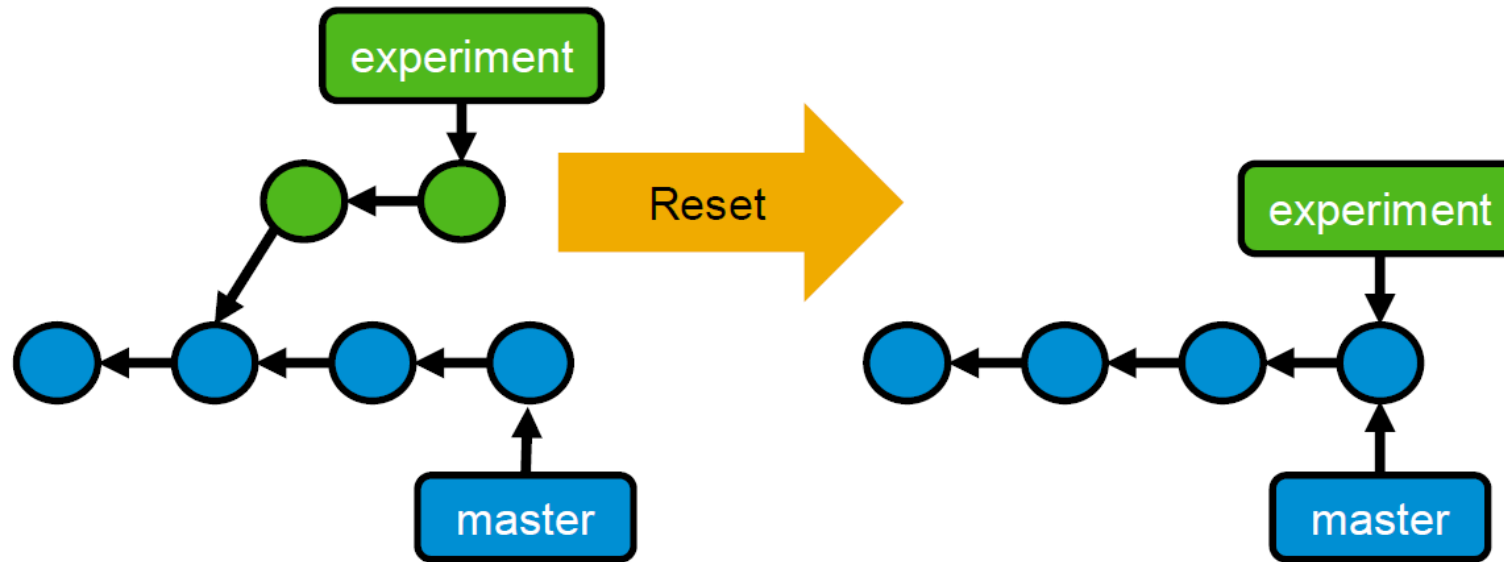

Rebasing with Conflicts

- ▶ Skip patch: skip this commit, resume the rebase with the next commit.
- ▶ Abort: back to the state before you started rebasing
- ▶ Continue: the usual choice, do this only *after* you've resolved the conflict
- ▶ Reset: cancel the rebase, move branch pointer to branch onto which you're rebasing

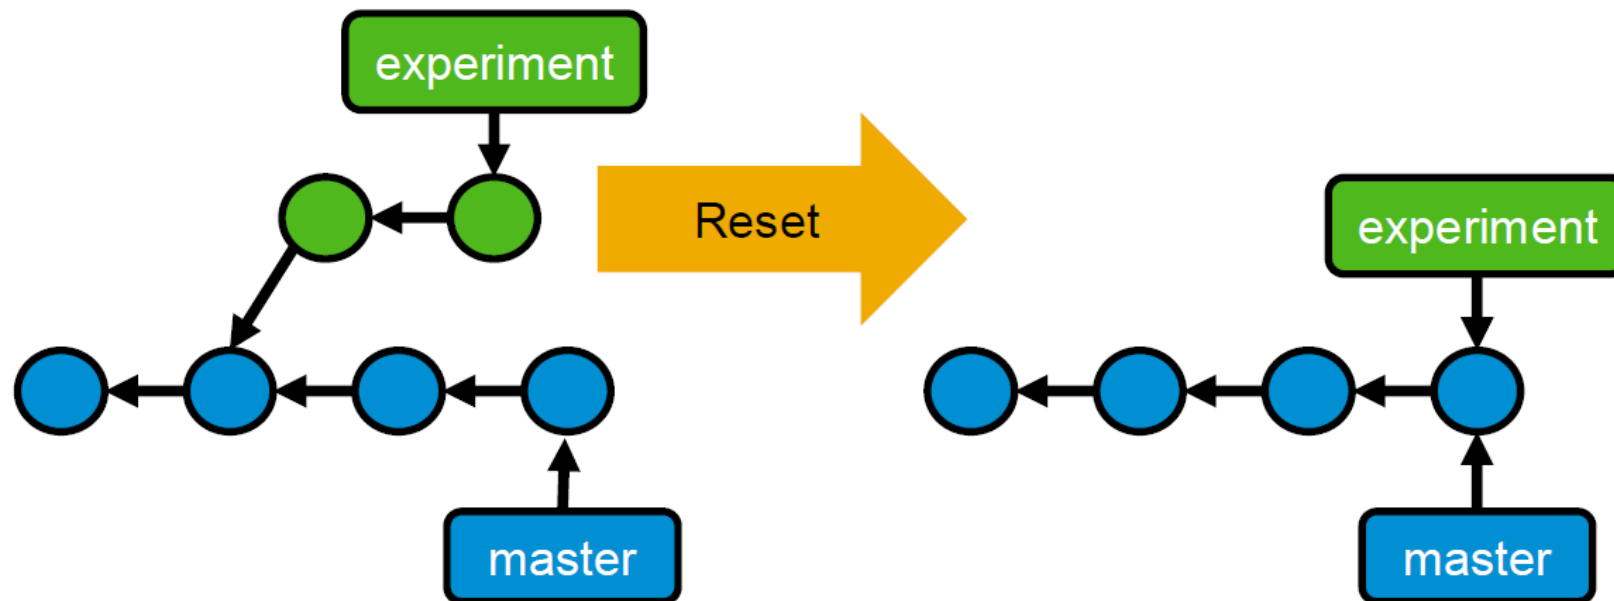

Hard Reset

- Moving a branch pointer, and losing all commits on old branch

Mixed Reset

- ▶ Retain all changes between 2 two original commits and turns them into unstaged changes.
- ▶ The difference includes the uncommitted changes in your working area (both staged and unstaged)

Extra tools: Cherry-Picking

- Take a single commit and copies it directly onto to any branch

Push

► Update remote repo

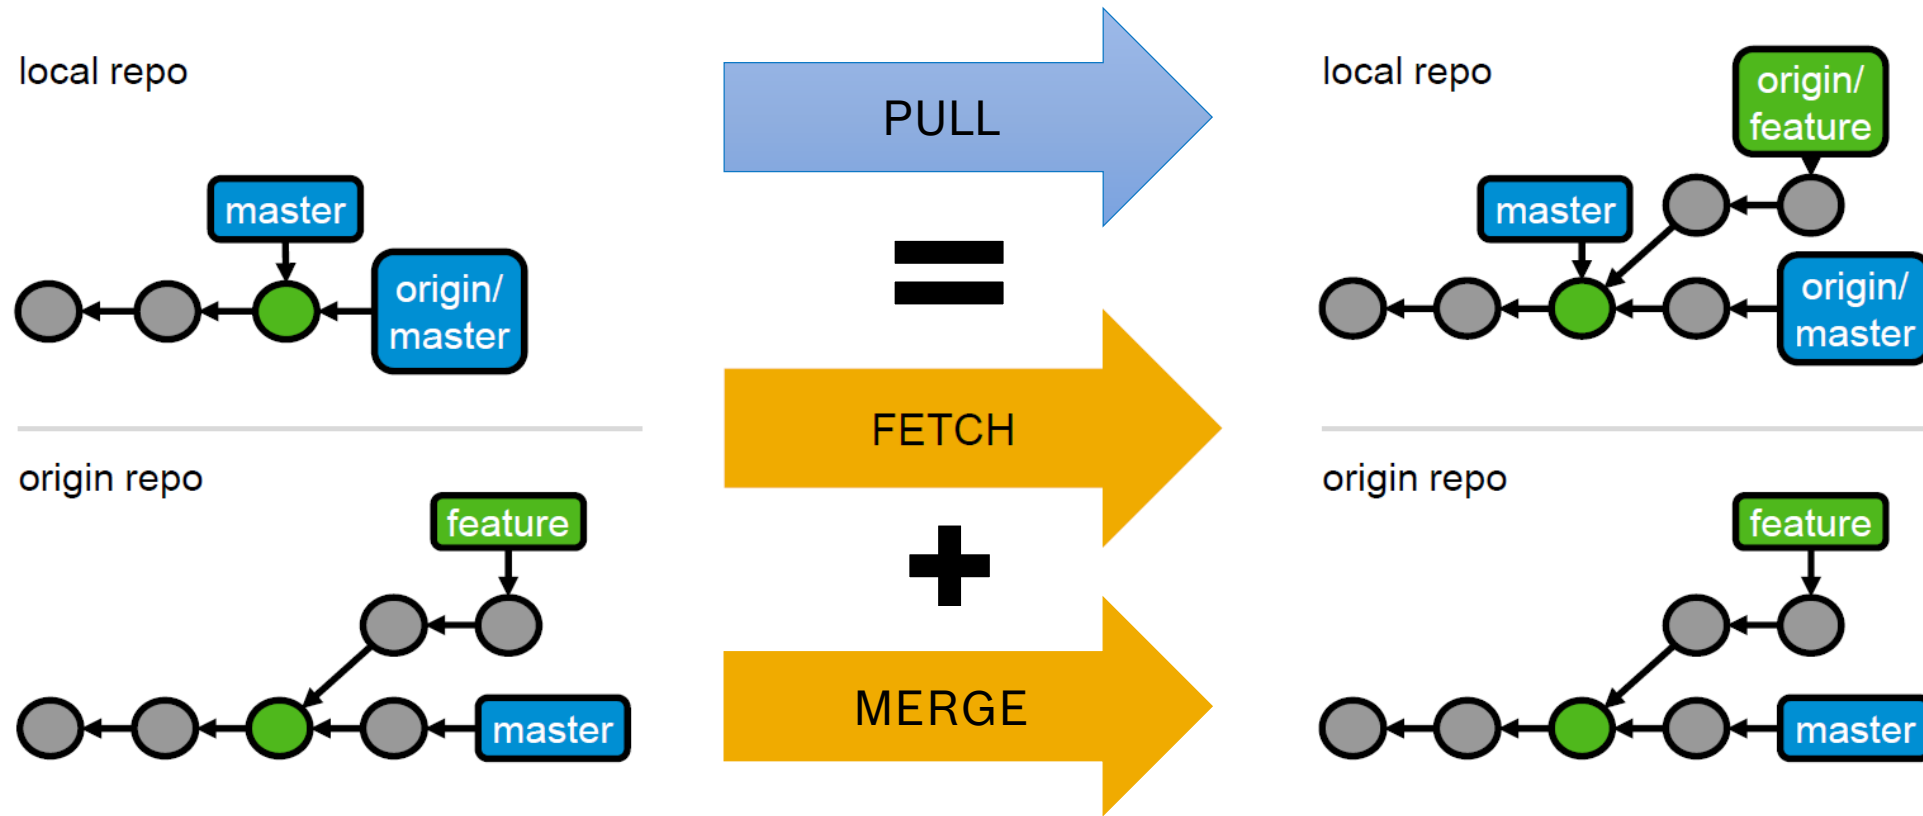

Fetching

- Update all remote branch on local repo

Pull = Fetch & Merge

- Do a Fetch (Update all remote branch on local repo), then MERGE the local branch onto remote **default** branch.

SSF Branches discussion

▶ Commit description convention:

- ▶ HPALM: Defect-XXX
- ▶ SMT: INCXXX
- ▶ Sprint: BR-XXX
- ▶ One commit for one task only.

▶ Remote repository purpose:

- ▶ origin/master: stable version (commits are used for **Go-live**; Defect; Incident; Translation)
- ▶ origin/dev_odd: sprint development (commits are used for Sprint), including defect fix
- ▶ origin/dev_even: latest Sprint developer
- ▶ origin/bugfix: Fix urgent bug. (before Go-live only)
